A. Personal Statement

We study the intrinsic and extrinsic mechanisms that regulate stem cell self-renewal (particularly in the hematopoietic system) and the role these mechanisms play in cancer (particularly leukemia and melanoma). Self-renewal is the process by which stem cells divide to make more stem cells, perpetuating stem cells throughout life to regenerate tissues. We discovered a series of key regulators that distinguish stem cell self-renewal from the proliferation of restricted progenitors in the same tissues. We also identified ways in which self-renewal mechanisms change with age, conferring temporal changes in stem cell properties that match the changing growth and regeneration demands of tissues. This may explain why the mechanisms that are competent to cause cancer also change with age. In terms of cell-extrinsic mechanisms, we identified the location and cellular composition of hematopoietic stem cell (HSC) niches in adult bone marrow and spleen, and discovered the Leptin Receptor⁺ perivascular stromal cells that are the major source of factors required for HSC maintenance in the bone marrow. The LepR⁺ cells also include the skeletal stem cells that are the major source of osteoblasts and adipocytes in adult bone marrow. We showed that distinct skeletal stem cell populations in the bone marrow (LepR⁺) and periosteum (Gli1⁺) make distinct contributions to bone maintenance and repair. In this way, the skeleton takes a different strategy than the hematopoietic system, distributing responsibility for tissue maintenance and repair across multiple spatially distinct stem cell populations. In terms of cancer, we discovered that distant metastasis by melanoma cells is limited by oxidative stress (which kills metastasizing cells by inducing ferroptosis) and that successfully metastasizing melanoma cells undergo reversible metabolic changes to cope with oxidative stress. We suggest that pro-oxidant therapies that exacerbate oxidative stress in cancer cells could be used to inhibit cancer progression.

Ongoing Research Support**001823**

Morrison (PI)

09/01/00 – 01/31/29

Howard Hughes Medical Institute

Funding is not associated with a specific project

RP180778

Morrison (PI)

08/31/18 – 08/30/22

Cancer Prevention and Research Institute of Texas
Metabolic enablers of melanoma progression – MIRA

This is a program project grant in which three laboratories (Morrison, DeBerardinis, and Mishra) will collaborate to study metabolic mechanisms that enable melanoma metastasis. The Morrison laboratory will study whether differences in oxidative stress, lactate metabolism, or mitochondrial function among melanomas from different patients confer intrinsic differences in metastatic potential.

R01DK11875 Morrison (PI) 04/01/19 – 03/31/24

NIH – National Institutes of Health

The Metabolic Regulation of Hematopoietic Stem Cell Function

To determine whether ascorbate (vitamin C) depletion, which is common among people in Western countries, promotes hematopoietic regeneration or clonal hematopoiesis and to identify the mechanisms by which ascorbate regulates hematopoiesis.

U01CA228608 Morrison (PI) 09/05/19 – 09/04/24

NCI – National Cancer Institute

The Metabolic Regulation of Melanoma Metastasis

The goal of this project is to compare patient-derived xenograft and patient-derived organoid assays to study the regulation of oxidative stress in melanoma cells.

U54CA268072 Danuser (PI) 09/24/21 – 08/31/26

NCI – National Cancer Institute

Imaging mechanisms of metastatic tumor formation in situ

The goal of this multi-PI project is to develop novel microscopes and assays that will allow us to image the earliest stages of metastasis, in patient-derived xenografts and in zebrafish embryos, to assess the mechanisms that determine the sites to which cancer cells are able to migrate and proliferate.

Kleberg Foundation Zon (PI) 01/01/22 – 12/31/25

New therapeutic strategies to modulate bone marrow inflammation in clonal hematopoiesis and leukemia

The overall goal for the team of investigators, Leonard Zon (Boston Children's Hospital), Ross Levine (MSKCC), Sean Morrison (UTSW) is to study niche mechanisms that regulate inflammation to better understand the role of inflammation in clonal dominance and leukemia development.

RP220492 Morrison (PI) 03/01/22 – 02/28/25

Cancer Prevention and Research Institute of Texas

Mechanisms of melanoma metastasis

The overall goal is to determine whether metastasizing melanoma cells undergo temporal or spatial changes in lipid metabolism, lipid ROS levels, or sensitivity to ferroptosis during metastasis.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

C. Contributions to Science

Stem cell self-renewal is regulated by networks of proto-oncogenes and tumor suppressors: When I started my laboratory in 1999 virtually nothing was known about the molecular mechanisms that regulate stem cell self-renewal. We developed assays to study self-renewal in hematopoietic stem cells (HSCs) and neural stem cells and identified a series of key regulators, revealing several important principles. First, stem cell self-renewal is mechanistically distinct from restricted progenitor proliferation. Second, many self-renewal mechanisms are conserved across stem cells in different tissues. Third, these mechanisms comprise networks of proto-oncogenes and tumor suppressors that are dysregulated in cancer: cancer cells tend to hijack stem cell self-renewal mechanisms to enable tumorigenesis. Fourth, these networks change over time, conferring temporal changes in stem cell properties that match the changing growth and regeneration demands of tissues. Fifth, tumor suppressor expression increases with age in stem cells, suppressing the development of cancer but also reducing stem cell function and tissue regenerative capacity. Finally, stem cells are metabolically distinct from restricted progenitors and depend upon metabolic regulation for epigenetic control and cancer suppression.

Ascorbate regulates haematopoietic stem cell function and suppresses leukaemogenesis. **Nature** 549:476-481. PMID28825709

The regulation of temporal changes in stem cell properties, including stem cell aging: Stem cells must undergo temporal changes in their properties throughout life to match the changing growth and regeneration demands of tissues. Stem cells in fetal tissues proliferate rapidly to support the growth of fetal tissues while stem cells in most adult tissues are quiescent most of the time. While stem cells in young adult tissues retain robust regenerative capacity, this declines over time in aging tissues. We discovered that networks of heterochronic gene products regulate temporal changes in stem cell properties between fetal and adult stages as well as during stem cell aging. For example, *Hmga2* expression declines while *let-7* expression and *Ink4a* expression increase with age, reducing stem cell frequency and function in multiple tissues. By deleting *Ink4a* from mice, we partially rescued the decline in stem cell function with age and enhanced the regenerative capacity of aging tissues. Networks of proto-oncogenes and tumor suppressors thus change throughout life to balance tissue regeneration with tumor suppression: proto-oncogenic signals dominate during fetal development when tissue growth is rapid but cancer risk is low, and tumor-suppressor mechanisms are amplified during aging when cancer risk is high. This provides one explanation for why regenerative capacity declines during aging in tissues that contain stem cells.

The niche for hematopoietic stem cells: We identified the locations and cellular compositions of niches for HSCs in adult hematopoietic tissues. We were the first to propose that HSCs reside in perivascular niches within the bone marrow after discovering SLAM family markers that enhanced the purification of mouse HSCs and enabled their localization in the bone marrow and spleen (a). We showed that most HSCs reside adjacent to sinusoidal blood vessels in bone marrow and spleen (a, b, c). We discovered the Leptin Receptor⁺ perivascular stromal cells that express the highest levels of niche factors in the bone marrow (d) and showed that these cells and endothelial cells are the major sources of known factors required for HSC maintenance in bone marrow (d). We also showed that the niche changes in response to injury, with adipocytes becoming a major source of factors for HSC regeneration after myeloablation.

The identification and regulation of skeletal stem cells in adult bone marrow: The Leptin Receptor⁺ cells that we discovered as a key component of the niche for hematopoietic stem cells (HSCs) include the skeletal stem cells that are the main source of new osteoblasts and adipocytes that form in adult bone marrow (a). These cells are normally quiescent in adult bone marrow but are activated by diverse injuries, including fractures and myeloablation, to increase their production of osteoblasts and adipocytes in the bone marrow (a, b). We discovered a new bone-forming growth factor that is synthesized by Leptin Receptor⁺ cells and that is required for the maintenance of adult skeletal bone mass: Ostelectin/Clec11a (c). Ostelectin acts by binding to $\alpha 11\beta 1$ integrin on the surface of Leptin Receptor⁺ cells and promoting their differentiation into mature osteoblasts. Conditional deletion of either *Ostelectin* or *$\alpha 11$ integrin* from Leptin Receptor⁺ cells leads to accelerated bone loss in adult mice, identifying a new regulatory mechanism for the control of adult skeletal bone mass. Importantly, the Leptin Receptor⁺ cells arise in the bone marrow around the time of birth but are initially very rare and make little contribution to the formation or neonatal growth of the skeleton but are critical for the maintenance of the skeleton during adulthood.

Melanoma tumorigenesis and metastasis: We developed a xenograft assay in which single melanoma cells from patients can form tumors (a). This showed that cells with tumor-forming potential are abundant and phenotypically diverse in melanoma, demonstrating that the cancer stem cell model does not apply to some cancers. Melanomas spontaneously metastasize in this model, creating for the first time an assay in which the metastasis of patient-derived cells could be studied in vivo. We found that metastatic behavior in this xenograft assay correlates with metastatic behavior in patients. We used this xenograft model to characterize the mechanisms that regulate distant metastasis, discovering that cancer cells experience a dramatic increase in oxidative stress during metastasis, leading to the death of most metastasizing cells by ferroptosis (b, d). The rare cells that survive metastasis undergo reversible metabolic changes that confer oxidative stress resistance (b, c). Intrinsic metabolic differences among melanomas confer differences in metastatic potential (c). Our data suggest that melanomas tend to metastasize first to lymph nodes because the lymph protects from oxidative stress and confers ferroptosis resistance, increasing the ability of melanoma cells to survive subsequent metastasis through the blood (d).
